

## INSTITUTIONAL BRIEF

# CTB v4

## A regulated pre-clearing layer for multilateral commodity obligations

**Purpose:** Measure and remove legally compatible gross settlement before residual payment.

**First ask:** A 30-minute technical scoping call and permission to test anonymised historical obligations.

### The proposition

CTB validates which recurring trade obligations may enter the same netting set, calculates multilateral net positions and links residual settlement to prefunded balances and verifiable commodity title. It does not create a new currency and does not replace banks, CIPS, CBDC or other lawful settlement rails.

| ELIGIBILITY                 | NETTING                              | RISK                                    | TITLE                                  |
|-----------------------------|--------------------------------------|-----------------------------------------|----------------------------------------|
| Compatible obligations only | Residual positions under hard limits | Prefunding, margin and capped waterfall | ADC only against verified goods or ETR |

### The institutional problem

Cross-border commodity trades are often funded and settled as separate gross bilateral obligations. Where three or more recurring participants form a compatible obligation graph, this may create avoidable peak liquidity, repeated transfers, fragmented reconciliation and duplicated title checks. The opportunity is measured on real data; it is not assumed.

### Explicit non-claims

No new reserve currency or public token market. No immunity from sanctions, export controls, licensing or applicable law. No claim against future production. No guaranteed fee, settlement time or saving before replay evidence. No regulator-blind anonymity and no autonomous AI decisions.

### Decision requested

Nominate one business owner and one risk/legal contact for a scoping call. No confidential data is requested at the first meeting.

## EVIDENCE-FIRST ENTRY POINT

# Historical replay before any live pilot

**Objective:** determine whether a selected corridor contains material, legally compatible multilateral offsets before committing to infrastructure, licensing or live settlement.

## Bounded scope

3–7 recurring legal entities; 6–12 months of anonymised or pseudonymised obligations; no live funds, no title transfer and no production deployment. The minimum data describes value, currency, due date, legal entity, governing law, commodity, title/document state and settlement outcome.

## Five work packages

**1 Data and eligibility**

Agree the schema, privacy boundary and exclusion taxonomy. Map legally compatible candidate netting sets.

**2 Gross baseline**

Reconstruct transfer count, value, timing, peak funding, failures and reconciliation effort.

**3 Constrained replay**

Calculate residual positions under actual maturities plus debit, tenor, concentration and participant limits.

**4 Legal and operational screen**

Frame questions on netting, insolvency, title, licensing, tax, AML/CFT, sanctions, data and finality.

**5 Decision pack**

Report measured benefit, exceptions, risk resources, dependencies and a go/no-go recommendation.

## Core measures

Netting ratio; reduction in peak liquidity and transfer count; eligible share of the original graph; concentration and persistent-surplus exposure; legal, title, data and operational exceptions; and total cost after collateral, integration and compliance.

## Go / no-go gate

Proceed to shadow mode only if the replay shows material benefit, committed anchor participants, a credible legal route, verifiable title, settlement exits, named risk owners and a sponsor for the next gate. Otherwise stop without sunk infrastructure cost.
